Cloning and Analysis of the *Eg4CL1* Gene and Its Promoter from Oil Palm (*Elaeis guineensis* Jacq.)

(Pengklonan dan Analisis Gen Eg4CL1 dan Promoternya daripada Kelapa Sawit (Elaeis guineensis Jacq.))

YUSUF CHONG YU LOK, IDRIS ABU SEMAN, NOR AINI AB SHUKOR, MOHD NORFAIZULL MOHD NOR & MOHD PUAD ABDULLAH*

ABSTRACT

The empty fruit bunches of oil palm have been used as the raw material to produce biofuel. However, the lignin present in oil palm tissues hampers the enzymatic saccharification of lignocellulosic biomass and lower the yield of biofuel produced. Hence, various efforts were taken to identify the lignin biosynthetic genes in oil palm and to investigate their regulation at the molecular level. In this study, a lignin biosynthetic gene, Eg4CL1 and its promoter were isolated from the oil palm. Eg4CL1 contains the acyl-activating enzyme consensus motif and boxes I & II which are present in other 4CL homologs. Eg4CL1 was clustered together with known type I 4CL proteins involved in lignin biosynthesis in other plants. Gene expression analysis showed that Eg4CL1 was expressed abundantly in different organs of oil palm throughout the course of development, reflecting its involvement in lignin biosynthesis in different organs at all stages of growth. The presence of the lignification toolbox - AC elements in the 1.5 kb promoter of Eg4CL1 further suggests the potential role of the gene in lignin biosynthesis in oil palm. Together, these results suggested that Eg4CL1 is a potential candidate gene involved in lignin biosynthesis in oil palm.

Keywords: Biofuel; lignin; oil palm; promoter; 4CL

ABSTRAK

Tandan kosong buah kelapa sawit telah digunakan sebagai bahan asas untuk menghasilkan biofuel. Walau bagaimanapun, lignin yang terdapat dalam tisu kelapa sawit menghalang proses sakarifikasi enzimatik biojisim lignoselulosa dan mengurangkan hasil bahan api biologi yang dihasilkan. Oleh itu, pelbagai usaha telah diambil untuk mengenal pasti gen biosintesis lignin dalam kelapa sawit dan untuk mengkaji pengawalaturannya pada peringkat molekul. Dalam kajian ini, gen biosintesis lignin, Eg4CL1 dan promoternya telah dipencilkan daripada kelapa sawit. Eg4CL1 mengandungi motif konsensus enzim pengaktifan asil dan kotak I & II yang terdapat dalam homolog 4CL yang lain. Eg4CL1 berkelompok bersama dengan protein 4CL yang diketahui terlibat dalam biosintesis lignin dalam tumbuhan lain. Analisis pengekspresan gen menunjukkan bahawa Eg4CL1 diekspres dengan banyak dalam organ kelapa sawit yang berbeza pada semua peringkat pertumbuhan, mencerminkan penglibatannya dalam biosintesis lignin dalam organ yang berbeza pada semua peringkat pertumbuhan. Kehadiran peti alat lignifikasi - unsur AC dalam promoter Eg4CL1 1.5 kb selanjutnya menyokong potensi gen ini yang berperanan dalam biosintesis lignin pada pokok kelapa sawit. Secara keseluruhannya, keputusan kajian ini mencadangkan Eg4CL1 sebagai calon gen yang berpotensi terlibat dalam biosintesis lignin pada pokok kelapa sawit.

Kata kunci: Biofuel; kelapa sawit; lignin; promoter; 4CL

INTRODUCTION

The oil palm (*Elaeis guineensis* Jacq.) is widely cultivated in many countries including Malaysia, Indonesia, Central America and Sri Lanka. It was primarily cultivated as a source of edible oil. Apart from the production of edible oil, the empty fruit brunches have been utilized as feed stock for biofuel production (Ibrahim et al. 2015; Piarpuzán et al. 2011). Production of biofuel from empty oil palm fruit brunches involves the enzymatic saccharification of the lignocellulosic biomass to produce fermentable sugars. However, the hydrolysis of the lignocellulose is hindered by the presence of lignin in the oil palm biomass (Gao et al. 2014). Lignin is the most abundant polymer in plants following cellulose. It is produced through the polymerization of monolignols including the hydroxycinnamyl alcohols, coniferyl alcohol and sinapyl alcohol (Vanholme et al. 2010). These monolignols are synthesized through the phenylpropanoid pathway which consists of three main enzymes, namely phenylalanine ammonia-lyase (PAL; EC 4.3.1.5), cinnamate 4-hydroxylase (C4H; EC 1.14.13.11) and 4-coumarate: coenzyme A ligase (4CL; EC 6.2.1.12). Being an enzyme located at the branching point of the phenylpropanoid pathway, 4CL regulates the flux of the carbon from the general phenylpropanoid pathway into different branch pathways.

4CL catalyzes the conversion of hydroxycinnamates to its corresponding CoA esters, to produce the precursors required for the biosynthesis of a couple of important secondary metabolites, including lignin, flavonoids and stilbenes. In plants, 4CL is encoded by a gene family with varying numbers of family members as observed in different species, for instance, four copies of the 4CL gene are present in Arabidopsis thaliana (Soltani et al. 2006) and Physcomitrella patens (Silber et al. 2008), while five copies are in the Oryza sativa and Populus trichocarpa genomes (Gui et al. 2011; Hamberger et al. 2007). Within the 4CL gene family, functionally divergent members have been identified in many species such as Pueraria lobata (Li et al. 2014), Arabidopsis thaliana (Ehlting et al. 1999) and Populus tremuloides (Hu et al. 1998). Basically, there are two types of 4CL genes in plants, designated as type I and type II. The type I 4CL genes are responsible for lignification while the type II 4CL genes are involved in the biosynthesis of flavonoid compounds. Suppression of the type I 4CL genes led to a significant reduction in lignin content in different plants (Gui et al. 2011; Xu et al. 2011a), while overexpression increased the lignin content (Rao et al. 2015). On the other hand, suppression of the type II 4CL gene only led to a reduction in eugenol content in Ocimum sanctum, without affecting the lignin content (Rastogi et al. 2013). Judging by their peptide sequences, type II 4CLs are different from type I 4CLs owing to the presence of additional amino acid residues at the N-terminal regions of type II 4CLs. Nevertheless, both types of 4CL share common conserved motifs namely Box I 'SSGTTGLPKGV' and Box II 'GEICIRG' (Heath et al. 2002; Kumar & Ellis 2003; Li et al. 2014).

Characterization and study of the lignin biosynthetic genes allow one to identify the lignin regulatory switch, subsequently opening the gateway to manipulate the lignin content in plants. The lignin biosynthetic genes have been well studied in many other species such as rice, poplar and switchgrass (Gui et al. 2011a; Voelker et al. 2010; Xu et al. 2011a), but very little information of lignin biosynthesis in oil palm is available. Hence, the oil palm 4CL1 gene and its promoter was isolated in the present study and its expression pattern during oil palm development was evaluated. This study provided a gateway for a better understanding of lignin biosynthesis in oil palm.

MATERIALS AND METHODS

PLANT MATERIAL

Oil palm (*Elaeis guineensis* Jacq., variety *pisifera*, 367 P) leaf samples obtained from the Malaysian Palm Oil Board (MPOB) Kluang Research Station in Johor, Malaysia were used for the gene and promoter isolation. Various samples of *Elaeis guineensis* Jacq., variety *tenera* (*dura* × *pisifera* hybrid, 0.409) collected from the MPOB/UKM Research Station and Universiti Putra Malaysia in Selangor, Malaysia were used in the gene expression analysis.

NUCLEIC ACID EXTRACTION AND cDNA SYNTHESIS

Genomic DNA was extracted from oil palm root tissues using Carroll's method (Carroll et al. 1995) with minor modifications. Total RNA was isolated from the oil palm tissue according to the method described by Wang et al. (2005). The 5'-RACE cDNA template was synthesized using SMARTer RACE cDNA Amplification Kit (Clontech, USA) according to the manufacturer's instructions. The first strand cDNA used in other work was synthesized using Maxima First Strand cDNA Synthesis Kit (Thermo Scientific, USA).

GENE ISOLATION

The nucleotide sequences of the 4CL gene homologues from different plant species were retrieved from GenBank (NCBI, http://www.ncbi.nlm.nih.gov). The gene sequences were aligned by using the Clustal W method to determine the conserved or highly-similar regions of the 4CL gene. A degenerate primer (4CL-R primer: 5'- CCC TTG TAY TTG ATG AKC TCC TT -3') was designed to bind to a specific conserved or highly similar region of the 4CL genes. The Eg4CL1 gene fragment was amplified using the 5'-RACE approach. The PCR was performed in a reaction volume of 50 μ L containing 1× Taq Buffer, 2 mM MgCl₂, 0.2 mM dNTPs, 0.2 µM 4CL-R primer, 1× Universal Primer A Mix (supplied in the SMARTer RACE cDNA Amplification Kit), 250 ng 5'-RACE template, 1.25 unit Taq DNA Polymerase (Thermo Scientific, USA) and dH₂O. The PCR thermal cycling profile used was 95°C (3 min), followed by 95°C (25 s), 56°C (30 s), 72°C (50 s) for 30 cycles and 72°C (5 min).

Subsequently, the 3'-RACE method was performed to obtain the full-length cDNA sequence of *Eg4CL1*. The 50 μ L PCR mixture comprised of 1× *Taq* Buffer, 2 mM MgCl₂, 0.2 mM dNTPs, 0.2 μ M 4CL1 3'-RACE primer (5'- CTG AGA CTG GAC TAT CAC TGC CT -3'), 0.2 μ M Oligo d(T)-adaptor primer (5'- GGC CAC GCG TCG AGT AC(T)₁₈-3'), 250 ng cDNA, 1.25 unit *Taq* DNA Polymerase (Thermo Scientific, USA) and dH₂O. The PCR was run at 95°C (3 min); 35 cycles of 95°C (25 s), 60°C (30 s), 72°C (50 s); 72°C (5 min).

The full-length sequence of the *Eg4CL1* cDNA was further verified using a high fidelity DNA polymerase with proofreading activity. The PCR mixture contained 1× Phusion HF Buffer, 1.5 mM MgCl₂, 0.2 mM dNTPs, 0.3 μ M Eg4CL1-F primer (5'- GAG ACA AGA GAA TTG AAC CA -3'), 0.3 μ M Eg4CL1-R primer (5'- GGA TGG TCT CAT CCA CTT T -3'), 250 ng cDNA, 1 unit Phusion DNA Polymerase (Thermo Scientific, USA) and dH₂O in a total reaction volume of 50 μ L. The PCR thermal cycling profile used was 98°C (30 s), followed by 98°C (10 s), 55°C (20 s), 72°C (40 s) for 35 cycles and 72°C (5 min).

The targeted PCR products were excised and purified from the agarose gel using the QIAquick Gel Extraction kit (QIAGEN, Germany). The purified PCR products were cloned into the pGEM-T Easy vector (Promega, USA) and sequenced by First BASE Laboratories Sdn Bhd (Selangor, Malaysia).

ISOLATION OF Eg4CL1 PROMOTER

The promoter of *Eg4CL1* was isolated from the oil palm genome by using the inverse-PCR method described by Ochma et al. (1988). The first portion of the promoter was isolated from the self-ligated gDNA template prepared from the gDNA double digested with *Hin*dIII and *Xba*I. The inverse-PCR was carried out in a 20 µL PCR mixture containing 1× *Taq* Buffer, 2.0 mM MgCl₂, 0.2 mM dNTPs, 0.3 µM 4CL1pro-F1 primer (5'- CGC CTA CGG AGG CGA CCA TCT TC -3'), 0.3 µM 4CL1pro-R1 primer (5'- GGG CCC ATC GCA ATC AAT CGT TTA -3'), 8 ng ligated DNA, 0.5 unit *Taq* DNA Polymerase (Thermo Scientific, USA) and dH₂O. The PCR thermal cycling profile was as follow: 95°C (3 min), followed by 95°C (25 s), 62°C (25 s), 72°C (80 s) for 40 cycles and 72°C (5 min).

The second portion of the promoter was isolated by using the self-ligated template derived from the gDNA digested with *NcoI*. The 20- μ L PCR mixture comprised of 1× *Taq* Buffer, 2.0 mM MgCl₂, 0.2 mM dNTPs, 0.3 μ M 4CL1pro-F2 primer (5'- ATC AAT CAC CAA CCA AGA CGC C -3'), 0.3 μ M 4CL1pro-R2 primer (5'- GCG TGA TCG GAT GGA CAA AGT T -3'), 8 ng ligated DNA, 0.5 unit *Taq* DNA Polymerase (Thermo Scientific, USA) and dH₂O. The PCR was performed at 95°C (3 min); 40 cycles of 95°C (25 s), 58°C (25 s), 72°C (60 s); 72°C (5 min).

To verify the sequence of the *Eg4CL1* promoter, the promoter region was amplified with a high fidelity DNA polymerase. The PCR was performed in 50 μ L containing 1× Phusion HF Buffer, 1.5 mM MgCl₂, 0.2 mM dNTPs, 0.3 μ M pro4CL1-F primer (5'- CCA TGG TGT GAC CAC GGA A -3'), 0.3 μ M pro4CL1-R primer (5'- CGC AAT CAA TCG TTT AGA GAG AAA -3'), 200 ng gDNA, 1 unit Phusion DNA Polymerase (Thermo Scientific, USA) and dH₂O. The PCR thermal cycling profile used was 98°C (30 s), followed by 98°C (10 s), 65°C (20 s), 72°C (45 s) for 35 cycles and 72°C (5 min).

IN SILICO ANALYSIS

The molecular weight and the theoretical isoelectrical point (pI) of Eg4CL1 were predicted using the ProtParam tool at the ExPASy website (web.expasy.org/protparam). The protein domains in Eg4CL1 were searched for in the NCBI conserved Domain databases (Marchler-Bauer et al. 2010) and PROSITE. The multiple sequence alignment was performed using the ClustalW method in BioEdit version 7.0 (Hall 1999). The 4CL amino acid sequences used in the multiple sequence alignment including Pto4CL1 (AAL02145), Lp4CL2 (AAF37733),

Os4CL1 (NP_001061353) and At4CL2 (NP_188761) were retrieved from the NCBI databases. The Eg4CL1 protein structure homology modeling was performed by the SWISS-MODEL using the *Populus tomentosa* 4CL1 (3ni2A) (Hu et al. 2010) as a template. The phylogenetic tree was reconstructed using the Neighbor-Joining method with bootstrap values set to 1000 in the MEGA5 software (Tamura et al. 2011). The 4CL amino acid sequences used for the phylogenetic analysis and the NCBI accession numbers of the sequences are presented in Supplementary Table 1. The *cis*-acting elements present on the promoter sequence of *Eg4CL1* were searched from the PlantCARE online database (Lescot et al. 2002) and other literatures.

GENE EXPRESSION ANALYSIS

A two-step RT-PCR was carried out to investigate the expression behaviors of the *Eg4CL1* gene in several organs including coleoptile and root of the germinating seeds; young leaf and young root of one-year-old palms; and immature fruitlet and young fruit of mature oil palms. The oil palm *GAPDH* gene (accession number: DQ267444) was used as the internal control for the analysis. A 20 μ L PCR mixture consisting of 1× *Taq* Buffer, 2 mM MgCl₂, 0.2 mM dNTPs, 0.2 μ M forward primer, 0.2 μ M reverse primer, 100 ng cDNA, 0.5 unit *Taq* DNA Polymerase (Thermo Scientific, USA) and dH₂O was prepared. The primers for this analysis are listed in Table 1. The RT-PCR was performed as follows: 95°C (3 min); 95°C (20 s), 58°C (25 s), 72°C (25 s) for 28 cycles; 72°C (5 min).

RESULTS

GENE ISOLATION

A full-length cDNA encoding for 4-Coumarate:Coenzyme A Ligase was isolated from the oil palm genome and deposited in GenBank under accession number KM234973. Since this is the first isolation and study of the 4CL gene in oil palm, this gene was designated as Eg4CL1. The Eg4CL1 cDNA was 1946 bp long and contained a 1623 bp open reading frame, flanked by a 5'-UTR of 55 bp and a 3'-UTR of 268 bp. The putative plant polyadenylation signal (5'-AATAAA-3') was found in the 3' UTR, located 5' upstream of the poly-A tail. The deduced translation product of Eg4CL1 consisted of 540 amino acids with a predicted molecular weight of 58.64 kDa and a theoretical isoelectric point of 5.67.

IN SILICO ANALYSIS

The Eg4CL1 gene exhibited high similarity with the 4CL from angiosperms, especially those from monocots. The BLAST in NCBI showed that Eg4CL1 shared high identities with several members of the 4CL gene family from Phoenix dactylifera (date palm) and Musa acuminata (banana). The highest identity was shown by the date palm 4CL2-like gene (LOC103718393) at 93%, followed by another date palm 4CL2-like gene (LOC103707092) at 78% identity. Eg4CL1 also shared 77% and 76% identities with banana 4CL3 (LOC103998718) and banana 4CL2 like-gene (LOC103973145), respectively, at the nucleic acid level. The multiple sequence alignment of the type I 4CL amino acid sequences showed that Eg4CL1 shared certain conserved regions with the 4CLs from the other plants (Figure 1). Notably, several protein domains including the box I (SSGTTGLPKGV) and box II (GEICIRG) motifs found in other plant 4CLs were also present in the Eg4CL1 (Figure 1). The active site residues (marked with blue dots) previously identified in the 4CL1 of Populus tomentosa (described as Pto4CL1 in this paper) based on its crystal structure and mutagenesis experiments are identical with Eg4CL1 (Figure 1). However, there are some variations in the substrate binding pocket residues (marked with green triangles) between Pto4CL1 and Eg4CL1. The Lys³⁰³ and Gly³⁰⁶ residues in the substrate binding pocket of Pto4CL1 appeared as Met³⁰³ and Ala³⁰⁶ in Eg4CL1. Hence, it is speculated that Eg4CL1 might show different preferences of substrates and catalytic efficiencies towards particular substrates compared to Pto4CL1. By using the conserved domain search in the Conserved Domain Database, the active site of 4CL, AMP binding site, putative CoA binding site and acylactivating enzyme consensus motif were detected in Eg4CL1. Moreover, the putative AMP-binding domain signature with the consensus sequence LPYSSGTTGLPK was detected by PROSITE. Together, the results of the analysis above support that Eg4CL1 is the putative 4CL1gene in oil palm.

PROTEIN STRUCTURE

Apart from the amino acid sequence analysis, computer predictions of the secondary structure and the threedimensional structure of the Eg4CL1 protein were also performed. The Self-Optimized Method with Alignment (SOPMA) website in ExPASy showed that the Eg4CL1 protein predominantly consisted of random coil (42.22%), followed by alpha helix (31.48%) and extended strand (18.70%), while the beta turn only contributed 7.59%. The three-dimensional structure of the Eg4CL1 protein was similar to that of Pto4CL1, which comprised of the larger N-domain and the C-domain (Figure 2). The catalytic residues of the 4CL gene are located within the C-domain (yellow). The N-domain which contains the substrate

FIGURE 1. Sequence alignment of Eg4CL1 with other type I 4CL amino acid sequences. Sequences used in the alignment were from *Elaeis guineensis* (Eg4CL1), *Populus tomentosa* (Pto4CL1), *Lolium perenne* (Lp4CL2), *Oryza sativa* (Os4CL1) and *Arabidopsis thaliana* (At4CL2). Box I and Box II are two highly conserved motifs for an AMP-binding domain. Amino acid residues involved in substrate binding are marked with triangles (▲) at the bottom, while those required for catalytic activities are indicated with circle (●). The identical amino acid residues are highlighted in yellow

FIGURE 2. 3-Dimensional protein structure of Eg4CL1. The 4CL consists of C-domain (yellow) and a larger N-domain which can be divided into three subdomains namely: N1 (blue), N2 (red) and N3 (green)

binding pocket is further divided into three subdomains which are: N1 (blue), N2 (red) and N3 (green). All of the domains are positioned at the right spots according to the protein structure of Pto4CL1.

PHYLOGENETIC ANALYSIS

The phylogenetic tree divided the 4CLs into two major clades which separated members of the type I 4CL from members of the type II 4CL (Figure 3). Members of type I 4CL were further divided into two distinct subclades representing the dicots and monocots. Two subclades were also observed within members of type II 4CL; in which one clade consists of members from the dicot, while another consist of members from the monocot. Eg4CL1 (indicated with a closed circle in Figure 3) was grouped together with other members of the type I 4CL from the monocots. Members of this clade are suggested to be involved in lignin biosynthesis and some of these 4CL genes have been characterized by functional studies. For instance, functional studies of the Pv4CL1 and Os4CL3 genes showed that they are involved in lignin biosynthesis in switch grass and rice, respectively. Perturbation of these 4CL genes resulted in reduced lignin content accompanied by profound phenotypic changes in transgenic plants (Gui et al. 2011; Xu et al. 2011a). Hence, the phylogenetic tree provides a hint that Eg4CL1 is the key enzyme involved in the lignin biosynthesis pathway in oil palm.

GENE EXPRESSION ANALYSIS

Despite the phylogenetic analysis providing a clue regarding the function of Eg4CL1, gene expression analysis was also performed to further characterize the Eg4CL1

gene. Since the expression behaviors of a gene reflect its physiological roles, the expression behaviors of Eg4CL1were investigated in several major organs of the oil palm including the coleoptile and root of the germinating seed; the young leaf and young root of one-year-old palm; and the immature fruitlet and young fruit. The RT-PCR showed Eg4CL1 was abundantly expressed in all of the oil palm organs studied at similar expression levels regardless of the developmental stages of the oil palm (Figure 4). The expression pattern of Eg4CL1 indicated that this gene might play an important role in lignification of the plant throughout the course of the oil palm development. By looking at the information from the phylogenetic analysis and the gene expression analysis, we postulate that Eg4CL1is responsible for lignin biosynthesis in oil palm.

PROMOTER SEQUENCE OF Eg4CL1

Since the expression behavior of a gene is largely regulated by its promoter, the isolation the Eg4CL1 promoter could show the identity of the regulating elements which may be involved in coordinating the expression of Eg4CL1. A fragment of 534 bp corresponding to the promoter sequence of Eg4CL1 was amplified in the first attempt. The second attempt produced another fragment (1262 bp) of the Eg4CL1 promoter sequence, combining these two fragments yielded the 1.521 kb promoter sequence of Eg4CL1. The transcription start site (TSS) of Eg4CL1 was identified based on the result of the 5'-RACE of Eg4CL1and defined as '+ 1'. It is an adenine nucleotide located 55 nucleotides upstream of the start codon. There are several motifs analogous to the TATA box found in the 5'- flanking sequence. However, the most probable TATA

FIGURE 3. Phylogenetic analysis of 4CL proteins from selected angiosperm species. The Eg4CL1 is indicated with a closed circle (•). The phylogenetic tree was constructed using Neighbor-Joining method with 1000 bootstrap replicates in MEGA5 software. The values on each branch represented the bootstrap percentages. The AtAAE (*Arabidopsis thaliana* acyl-activating enzyme 13/ malonate--CoA ligase) was used as the outgroup. The complete scientific name of the organisms and the NCBI accession numbers of the 4CL proteins used in this analysis are presented in Supplementary Table 1

FIGURE 4. Expression profile of the *Eg4CL1* gene in different organs of oil palm. Total RNA from coleoptile (Ct) and primary root (Pr) of germinated seeds, young leaf (Yl) and young root (Yr) of one year old oil palm, immature fruitlet (If) and mesocarp tissues of young fruit (Fr) were converted to cDNA and

subjected to RT-PCR

box has the sequence 'TATATTA' located at the position of -31 upstream of the TSS. Several important *cis*-acting elements including phytohormones-responsive elements, light-responsive elements, tissue-specific activation motifs and stress-responsive elements were detected in the promoter of *Eg4CL1* (Table 2). Among these *cis*-acting elements, the AC-II (ACCAACC) element was present twice at the -117 and -326 positions 5' upstream of the *Eg4CL1* gene (Supplemental Figure 1, online resource). The AC elements are the most prominent *cis*-acting element present in the promoter of the lignin biosynthetic genes including the *PAL*, *4CL* and *CAD* genes (Raes et al. 2003; Xu et al. 2014). It serves as the binding site for the MYB transcription factors involved in the regulation of the gene expression. Furthermore, AC elements are also necessary for the xylem specific expression of the lignin biosynthetic genes (Hatton et al. 1995).

DISCUSSION

In this study, a full-length cDNA of Eg4CL1 which encodes 4-Coumarate:coenzyme A ligase was isolated from the oil palm genome. Phylogenetically, the Eg4CL1 gene is classified as a type I 4CL gene which is responsible for the biosynthesis of lignin. The Eg4CL1 was expressed abundantly in all the oil palm organs studied, indicating it plays an important role in the production of monolignols for lignin biosynthesis in oil palm tissues. The presence of the lignification-regulating *cis*-acting elements in the promoter sequence of Eg4CL1 further implies the involvement of this gene in lignin biosynthesis. Together

TABLE 2. Cis-acting elements present in the promoter of Eg4CL1

the information from the coding region, promoter, phylogeny and expression of the gene suggested that Eg4CL1 is involved in lignin biosynthesis in the oil palm.

Lignin is a biopolymer which is deposited in the plant secondary cell wall (Neutelings 2011). It provides mechanical support to allow the plant to stand upright and confers defense against pathogen attacks (Xu et al. 2011b). However, the deposition of lignin in the plant cell does not favor industrial applications such as paper making and biofuel production. Removal of lignin from the pulp is costly and leads to the production of chemical wastes that are dangerous to the environment (Vanholme et al. 2010; Zhong & Ye 2009). For biofuel production, the presence of lignin in the lignocellulosic biomass impedes the saccharification process (Gao et al. 2014). Thus, reduces the amount of fermentable sugar produced and lowers the efficiency of biofuel production from the lignocellulosic biomass (Chapple et al. 2007; Chen & Dixon 2007). To overcome these problems, the lignin content of the plant biomass can be manipulated through genetic and molecular approaches (Shen et al. 2013; Van Acker et al. 2014).

The lignin biosynthetic genes such as *PAL*, *4CL*, *COMT* and *CAD* had been identified in many species and their roles were determined by functional studies (Chao et al. 2014; Gui et al. 2011; Huang et al. 2010; Trabucco et al. 2013). Manipulation of the lignin biosynthetic genes has been performed in a few economically important plant species to control the lignin content in the plant tissues (Jung et al. 2013; Sykes et al. 2016). Among the lignin biosynthetic genes in the phenylpropanoid pathway, *4CL* has become one of the targets to manipulate the lignin content of the phenylpropanoid pathway; channeling the CoA esters to form either flavonoids or lignin. In switch grass, suppression of the *Pv4CL1* gene resulted in reduced lignin

accumulation in the transgenic plants without affecting the biomass yield. Furthermore, the transgenic plants with reduced lignin content showed higher saccharification efficiency for biofuel production (Xu et al. 2011a). In *Populus tomentosa* Carr., perturbation of the *Ptc4CL1* gene led to changes in lignin content and composition in the transgenic plants. Up- and down-regulation of the *Ptc4CL1* gene shows that there is a positive correlation between the 4CL activity and lignin content in the plant (Tian et al. 2013a). In *Pinus radiata*, silencing of the *4CL* gene resulted in dwarfed plants with severe lignin reductions and changes in lignin composition and structure (Wagner et al. 2009).

The 4CL genes are present in most of terrestrial plants, ranging from the lower plants such as liverworts and mosses to higher plants (Gao et al. 2015; Hamberger & Hahlbrock 2004; Silber et al. 2008). The gene usually exists in multiple copies which are similar in their sequences (De Azevedo Souza et al. 2008). This occurred as a result of gene-duplication events in the past (Hamberger & Hahlbrock 2004; Hamberger et al. 2007). In certain plants, multiple copies of the gene demonstrated a redundant role. Ehlting et al. (1999) suggested that the At4CL1 and At4CL2 genes of Arabidopsis play a redundant role in lignin biosynthesis. Furthermore, Li et al. (2015) showed that the At4CL1 and At4CL3 genes of Arabidopsis were both involved in the biosynthesis of sinapoylmalate. In Populus tomentosa, its five Pto4CL genes also displayed an overlapping function in lignin biosynthesis (Rao et al. 2015). The existence of multiple 4CL genes could be viewed as a strategy to safe-guide the integrity of important metabolic pathways that serve for plant growth and development like lignification where a loss-of-function mutation in one copy of the gene could be rectified by another copy.

In general, the *4CL* genes of angiosperms can be classified into type I and type II, based on their sequence similarity (Hamberger et al. 2007). Both type I and type II *4CL* genes are sharing the same protein domains. Li et al. (2014) showed that the peptide sequences of Pl4CL1 and Pl4CL2 which represent the type II and type I *4CL* genes of *Pueraria lobata*, respectively, possessed the same Box I 'SSGTTGLPKGV' and Box II 'GEICIRG' conserved motifs of 4CL. Nevertheless, several studies have reported that the peptide sequences of the type II genes displayed an extension of amino acid residues at the N-terminal region compared to the type I 4CL (Heath et al. 2002; Hu et al. 1998; Kumar & Ellis 2003). This is a unique feature displayed by the type II *4CL* genes.

Apart from the Eg4CL1 gene reported in this study, another three 4CL genes (designated as Eg4CL2-4) were identified from the oil palm genome. Eg4CL2 is located on chromosome 2 together with Eg4CL1. Meanwhile, the Eg4CL3 and Eg4CL4 genes are located on chromosome 8 and 11, respectively (Supplementary Table 2). Our analysis also showed that Eg4CL2 and Eg4CL3 are clustered together with Eg4CL1 as type I 4CL gene, while Eg4CL4as type II 4CL gene (Supplementary Figure 2). Since detailed studies on *Eg4CL2-4* have not been performed, these genes would not be discussed further here.

The different types of 4CL genes served for different functions in plants. The type I 4CL genes are responsible for lignin biosynthesis, while the type II genes are involved in the formation of flavonoids and other metabolites (Ehlting et al. 1999; Li et al. 2014). For instance, At4CL1 (a type I 4CL) was abundantly expressed in the heavily lignified inflorescence stem in arabidopsis (Ehlting et al. 1999; Lee et al. 1995). The 4cl1 mutant was smaller in size and contained less lignin compared to the wild-type (Li et al. 2015). In contrast, the At4CL3 gene (a type II 4CL) was highly expressed in the flowers and siliques but not in the xylem (Ehlting et al. 1999; Li et al. 2015). Mutation of the At4CL3 gene did not affect the lignin content, but greatly reduced the anthocyanin content of the mutant (Li et al. 2015). In rice, the Os4CL3 gene (a type I 4CL) was found to be responsible for lignin biosynthesis, while its homolog, Os4CL2 (a type II 4CL) was involved in flavonoid production (Gui et al. 2011; Sun et al. 2013).

The phylogenetic tree reconstructed in this study showed that Eg4CL1 was clustered together with other type I 4CL genes from monocots such as Pv4CL1, Lp4CL2/3 and Os4CL1/3/4/5, implying that Eg4CL1 is also a type I 4CL and may carry out the same function as the other members of this clade. Previously, functional studies have been performed on Pv4CL1 and Os4CL3 to dissect their functions. Perturbation of Pv4CL1 and Os4CL3 led to lower lignin deposition accompanied by other phenotypic alterations in the transgenic plants (Gui et al. 2011; Xu et al. 2011a). Hence, Eg4CL1 is very likely involved in lignin biosynthesis in oil palm. Besides the phylogenetic analysis, expression behaviors of the gene also suggested that Eg4CL1 plays a major role in lignin production in oil palm. The gene expression analysis shows that *Eg4CL1* is highly expressed in all the tissues studied, including vegetative and reproductive organs, regardless of the developmental stage. The expression behaviors of the gene implied that *Eg4CL1* is associated with the onset of the biosynthesis of monolignols in oil palm tissues. In arabidopsis, At4CL1 was expressed in all of the organs including the leaf, root, inflorescence stem, flower and silique at the seedling and mature stages (Ehlting et al. 1999; Lee et al. 1995). The accumulation of the At4CL1 transcripts in the cotyledons and roots of the 3-days-old seedlings was correlated with the initiation of lignin biosynthesis after germination (Lee et al. 1995). Gene mutation analysis showed reduced lignin content in the 4cll mutant, which indicated that At4CL1 is responsible for lignin biosynthesis in arabidopsis (Li et al. 2015). The expression of Eg4CL1 in various tissues would allow the biosynthesis of lignin in various tissues for the development of the normal plant structure as lignin is required for the development of normal organ structure and provide mechanical support to the plant (Hirano et al. 2013; Yan et al. 2013). Therefore, the expression pattern of *Eg4CL1* indicates it plays an important role in lignin biosynthesis in oil palm tissues. Apart from that, the expression of Eg4CL1 may also be correlated directly with lignin biosynthesis in oil palm. A direct correlation between the expression of the lignin biosynthetic gene and the lignin content had been observed in previous studies (Fu et al. 2011; Voelker et al. 2010).

The expression behavior of a gene and its activities are mainly regulated by its promoter, although sometimes it may involve the participation of other gene elements such as intron and terminator (Goebels et al. 2013; Nagaya et al. 2009). To show the regulatory elements of the Eg4CL1 gene, the promoter region was isolated. In line with the gene expression behavior, the type of *cis*-acting elements present in the promoter of Eg4CL1 also suggests its functional role in lignin biosynthesis. As anticipated, the AC II elements were detected at two locations in the Eg4CL1 promoter. Previous sequence analysis showed that the AC elements are present in the regulatory region of most of the lignin biosynthetic genes including PAL, 4CL, COMT and CAD (Hamberger et al. 2007; Raes et al. 2003). The AC elements in the promoter region serve as the binding site for the MYB transcription factors to regulate the expression of the genes (Shen et al. 2012; Tian et al. 2013b; Wang et al. 2014). A study of the bean PAL2 promoter in transgenic tobacco has shown that the AC element is required for the xylem-specific expression of the lignin biosynthetic genes. Mutation of the AC element led to a reduced or complete loss of xylem specific expression in plants (Hatton et al. 1995). The presence of the AC II elements further supports the involvement of Eg4CL1 in lignin biosynthesis.

To further confirm the function of the *Eg4CL1*, functional analysis should be performed on the gene and the promoter through the transgenic approach. However, producing transgenic oil palm is technically difficult, inefficient and time consuming (Bahariah et al. 2013; Masani et al. 2014). Hence, this study provides some clues for the identification of the lignin-related *4CL* gene in oil palm. Identification of the lignin production regulatory switch in oil palm will permit the manipulation of lignin in oil palm will greatly improve the saccharification process and subsequently enhance biofuel production from oil palm empty fruit bunches.

CONCLUSION

In this study, the Eg4CL1 gene and its promoter region have been isolated from oil palm. According to the analysis performed, Eg4CL1 is potentially involved in lignin biosynthesis in oil palm. Therefore, Eg4CL1 can be served as a molecular switch to manipulate the lignin content in oil palm biomass. This would allow more efficient production of biofuels from oil palm empty fruit bunches.

ACKNOWLEDGEMENTS

This study was funded by the Malaysian Palm Oil Board (Grant no.: 6366800). The authors would like to thank Prof. Dr. Ho Chai Ling for providing the 5'-RACE cDNA

template and Mdm. Yeoh Keat Ai for her assistance in the preparation of the 5'-RACE cDNA template. Special thanks go to Mr. Rosmidi b. Miswan for his involvement in collection of oil palm samples. Finally, we are indebted to Prof. Dr Tan Soon Guan for proofreading the entire manuscript promptly. MPA, NAAS and IAS conceived and designed the research. YCYL and MNMN conducted the experiments. YCYL and MPA analyzed data. YCYL wrote the manuscript. All authors read and approved the manuscript. The authors declare that they have no conflict of interest.
